Abstract

Small Cu-Mo ore deposit near Vidly pod Pradědem (2.5 km south of Vrbno pod Pradědem, Czech Republic) is formed by ore disseminated in polyphase-metamorphosed blastomylonites of the Orlík Block nappe. A rare local occurrence of Bi minerals whose aggregates do not exceed 600 µm, is restricted mainly to small grains (< 2 - 200 µm in size) hosted by pyrite or within boundaries between pyrite and chalcopyrite. Pilsenite is a dominating mineral phase, joséite-A, joséite-B, native Bi, tsumoite and tetradyomite are less frequent. Cosalite containing ~ 4 wt. % Ag and solid solution phases lillianite - gustavite (4 to 8 wt % Ag) are frequent too. The origin of the assemblage of Bi minerals can be linked to the metamorphic processes in the wider area. In the Jeseníky Mts., the Bi minerals of the same genetic position have been described from Zlaté Hory and Zlatý Chlum near Jeseník deposits.

Key words: Bi-Te-minerals, sulphides, mineralogy, chemistry, metamorphogenic association, Jeseníky Mts.
